1. Abstract
Congenital diverticular are rare and caused from weakening of the bladder mucosa with the entire wall of the diverticulum. Giant vesical diverticulum are uncommon and total of 13 cases reported. The gold standard of treatment this bladder diverticulum is with extravesical diverticulectomy approach. We would like to report a case of renal cell carcinoma with concurrent giant bladder diverticulum. This will be the first case report on the laparoscopic extravesicle approach done concurrent in a renal malignancy patient who has proved to be safe, effective, and minimally invasive and therefore superior to open extravesical diverticulectomy which is the gold standard.

2. Introduction
Congenital diverticular are rare and caused from weakening of the bladder mucosa with the entire wall of the diverticulum. Giant vesical diverticulum is uncommon and total of 13 cases reported. A 76 years old Chinese gentleman presented with abdominal distention and lower urinary symptoms. CT renal 4 phases showed right RCC with large urinary bladder diverticulum. We would like to report a case of renal cell carcinoma with concurrent giant bladder diverticulum. This will be the first case report on the laparoscopic extravesicle approach done concurrently in a renal malignancy patient who has proved to be safe, effective, and minimally invasive and therefore superior to open extravesical diverticulectomy which is the gold standard (Figure 1).

3. Case Report
76 years old Chinese gentleman presented with abdominal distention and pain over the lower quadrant for past 5 months. Patient also had lower urinary symptoms. Per abdomen was distended with a vague mass over the right lower quadrant measuring 15cmx15cm, non tender, non pulsating. Digital rectal examination prostate was enlarged with median sulcus obliterated. No nodule or mass palpable. We proceeded with ultrasound abdomen and showed a highly...
vascular right renal mass represents a renal cell carcinoma and a large urinary bladder diverticulum. CT renal 4 phase showed a lobulated enhancing mass at interpole of right kidney with a large well defined hypodense mass of fluid attenuation from superior urinary bladder suggestive of right RCC with giant urinary bladder diverticulum. We proceeded with laparoscopic right nephrectomy with diverticulectomy. The intraoperative finding was multiple nodules at right kidney, giant bladder diverticulum located at lateral part of the bladder wall. Patient had a speedy recovery and was discharge home with continues bladder catheter after day 10 of post operative. The Histopathology result of bladder wall specimen shows consistent with diverticulum with no evidence of malignancy. The renal specimen shows clear cell renal cell carcinoma with Fuhrman nuclear Grade 2 T1b N0 M0 (Figure 2, 3).

4. Discussion

Congenital diverticula usually occur in areas where there is insufficient muscle, typically at the ureterovesical junction, or between bundles of hypertrophied muscle. They are usually asymptomatic and are discovered incidentally. Open extravesical diverticulectomy approach is the conventional surgery performed. However, we performed a laparoscopic transvesical diverticulectomy approach. We would like to describe the surgical approach for a giant vesical diverticulum with concurrent renal cell carcinoma. From our literature search we have found 13 cases of “giant bladder diverticulum”. All this giant bladder diverticulum was operated with open extravesical diverticulectomy. We have summarized this 13 cases based on the characteristics such as initial presentation, diagnosis and treatment approach (Table 1).

We would like to discuss the various technique and approach which are available for giant bladder diverticulum. As for most urologists, surgical excision by mean of open surgical technique remains the most common treatment option. Open bladder diverticulectomy can be performed either extravesical, intravesical, or combination approach [14].

However, our patient we have chosen laparoscopic method over open surgery because this patient had right renal cell carcinoma which requiring nephrectomy. Laparoscopic bladder diverticulectomy represents a minimally invasive alternative to the open approach. It can be performed either transperitoneal or extraperitoneally. The principle for laparoscopic diverticulectomy is the same as for open diverticulectomy approach.

Laparoscopic transperitoneal technique for bladder diverticulectomy was described by Gill. This technique involves insertion of four or five transperitoneal laparoscopic ports. Followed by selective distension of the diverticulum. An incision at the peritoneum is made over the diverticulum. A circumscription of the neck and excision of the diverticulum at its ostium. The bladder is closed in two layers [15]. Meanwhile, Laparoscopic extra peritoneal technique for bladder diverticulectomy was first described by Nadler et al. in a patient with a 300 mL diverticulum. The principles of bladder diverticulectomy is the same as, described above. A 2 cm incision is made below the umbilicus, which was used to introduce the surgeon’s finger. A self made dilating balloon catheter was used to create a retroperitoneal space. The dilating balloon was inflated with 1000 mL of normal saline to accomplish this. Four laparoscopic ports was then inserted. They dissected the diverticulum emanating just lateral the right ureteral orifice. Since then, only a few other cases using this technique have been reported [17-19].

We have choosen the extravesicle approach instead of intravesicle approach. This was because we wanted to avoid a separate cystotomy incision to inspect the bladder lumen. Beside that this was a renal cell carcinoma patient. This technique allows the urologist...
to visualise directly the location of the neck of diverticulum within the bladder lumen. The extravesical approach was described by Nerli et al [20]. We used laparoscopic method to identify the bladder diverticulum. We then inserted a continious bladder drainage to collapse the diverticulum. The neck of diverticulum was identified. The laparoscopic cautery device was then used to score the extravesical surface to mark the site of the incision on the bladder. A circumferentially incision was made around the lesion with a 4-5 cm margin. Followed by making a full-thickness bladder incision using cautery. A complete excision of bladder pathology with a healthy margin of bladder wall is essential in order for a success operation. The advantages of this technique include the lack of a second cystotomy site thus requiring fewer bladder closures and less risk of post-operative urinary leak (Table 1).

However, beside the extravesicle approach there is a the intravesical approach which was first described by Mariano and tefilli. They performed a small cystotomy which was made on the bladder dome. With the Foley catheter clamped, the pneumoperitoneum entered the bladder and rapidly distended it. The laparoscope and instruments entered then be advanced into the distended bladder. Excision of the bladder lesion was then performed under direct vision through the cystotomy [21]. The advantage of this technique is its simplicity. The disadvantages of this approach was that creating a larger transverse cystotomy defect in order to insert several instruments. This cystotomy itself must be large enough to accommodate them. This may result in difficulty to close the wound and thus a higher risk or post-operative urine leakage.

5. Conclusion
In our experience, this is the first case report on the laparoscopic extravesicle approach was done concurrently in a renal malignancy patient which have proved to be safe, effective, and minimally invasive and therefore superior to open extravesical diverticulectomy which is still the gold standard.
